

# INTERTEMPORAL LABOR SUPPLY AND HUMAN CAPITAL ACCUMULATION

SUSUMU IMAI AND MICHAEL P. KEANE

December 2000

# Intertemporal elasticity of substitution in labor supply

- This has long been an area of study, see Lucas and Rapping 1969
- Studies using micropanel data in structural models include MaCurdy 1981, Browning, Deaton, and Irish 1985, and Altonji 1986.
- Are unable to solve a puzzle: although wages grow throughout the life cycle, hours worked do not
  - Why don't workers work less when young and wages are low and more when they are old and wages are high?

# Human capital

- The answer: wages are determined by human capital which grows with work experience
- Workers face competing motivations: wages grow through the life cycle, but returns to human capital decrease
  - The result is a relatively flat labor supply (see next slide)
- Previous research which does not account for human capital thus underestimates the elasticity of labor supply
- Our model will correct this

# Agent's problem

Agents maximize their discounted expected life-cycle utility through the working horizon  $T$ :

$$E_t \sum_{\tau=t}^T \beta^{\tau} [u(C_{\tau}, \tau) - v(h_{\tau} \epsilon_{2,\tau})] \quad (1)$$

subject to their intertemporal budget constraint:

$$A_{t+1} = (1 + r)A_t + W_{t,s}h_t - C_t \quad (2)$$

Equations (1) and equations (2) characterize the problem we want to examine.

# The human capital production function

NOTE: Only plot cells with at least 20 observations.

# Problem before shocks

Next period human capital before shocks are realized is:

$$\tilde{K}_{t+1} = g(h_t, K_t, t)$$

So we can rewrite the value function as:

$$V_{t,s}(A_t, \tilde{K}_t, \epsilon_{1,t}, \epsilon_{2,t}) = \max_{C_t, h_t} (u(C_t, t) - v(h_t, \epsilon_{2,t}) \\ + \beta E_t V_{t+1,s+1}(A_{t+1}, \tilde{K}_{t+1}, \epsilon_{1,t+1}, \epsilon_{2,t+1}))$$

# Emax function

Defining the emax function as:

$$V_{t+1,s+1}^E(A_{t+1}, \tilde{K}_{t+1}) = E_t V_{t+1,s+1}(A_{t+1}, \tilde{K}_{t+1}, \epsilon_{1,t+1}, \epsilon_{2,t+1}) \quad (3)$$

We can write the agent's problem before shocks are realized as:

$$V_{t,s}(A_t, \tilde{K}_t, \epsilon_{1,t}, \epsilon_{2,t}) = \max_{C_t, h_t} [u(C_t, t) - v(h_t, \epsilon_{2,t}) + \beta V_{t+1,s+1}^E(A_{t+1}, \tilde{K}_{t+1})]$$

# NLSY79

- ① Our data comes from the NLSY79
- ② Advantage over the PSID, used by MaCurdy 1981 and others, is that we can directly use asset data
- ③ Focus on white males who are at least 20 years old and have some schooling

# Mean wage profiles

Age	Hourly Wage	Hours	Total Wealth
20	5.785 (2763)	1531.7 (2837)	6334.8 (207)
21	5.998 (3220)	1578.6 (3348)	6178.5 (568)

# Intertemporal elasticities

- Estimate the intertemporal elasticity of labor supply of 3.82, much closer to that from the macro literature (eg Eichenbaum, Hansen, and Singleton 1988)
- Estimate an i.e.s.-c of -1.354
- This contrasts with the common estimate of  $-1/3$  (see Hubbard, Skinner, and Zeldes 1994)
- Ignoring human capital biases IEL downwards and explains the dissonance between micro- and macro-estimates
